STUDIES RELATED TO WILDERNESS

Bureau of Land Management Wilderness Study Areas

The Federal Land Policy and Management Act (Public Law 94-579, October 21, 1976) requires the U.S. Geological Survey and the U.S. Bureau of Mines to conduct mineral surveys on certain areas to determine their mineral values, if any. Results must be made available to the public and be submitted to the President and the Congress. This report presents the results of a geochemical survey of the Gold Creek (OR-003-033) and the Sperry Creek (OR-003-035) Wilderness Study Areas (WSAs), Malheur County, Oregon.

INTRODUCTION

In August 1988, the U.S. Geological Survey conducted a reconnaissance geochemical survey of the Gold Creek and the Sperry Creek WSAs, Malheur County, Oregon. The Gold Creek WSA comprises 24.6 mi^2 (63.8 km^2) (15,780 acres), and the adjacent Sperry Creek WSA covers 8.7 mi^2 (22.7 km^2) (5,600 acres). The study areas are located about 35 mi (56.3 km) southwest of Vale, Oregon along U.S. Highway 20 and lie immediately south of the highway and the Malheur River. Access is by a good ranch road up South Trail Creek and a poor ranch road between Spring and Sperry Creeks. The south side of the area is accessed by jeep trails over rough ground or from a dirt road connecting Harpers Junction and Crawley via Cottonwood Canyon. Upper Simmons Gulch can be reached via a jeep trail that branches off the Squaw Creek road where it connects with Highway 20.

The topographic relief in the study area is about 2,680 ft (817 m), with a maximum elevation of 5,322 ft (1,622 m) in the southwest corner of the Gold Creek WSA and a minimum elevation of 2,640 ft (805 m) along the Malheur River at the northeast corner of the Gold Creek WSA. Except in the gently sloping uplands of the southwest corner of the Gold Creek study area, the topography is rugged with deep canyons. This is a semi-arid region with sparse vegetation on the hillsides and uplands, but with dense vegetation along the streams. Stream flow is intermittent within the WSAs but pools were noted along most stream courses in August.

The WSAs lie in a tertiary volcanic terrain dominated by basalt flows along the northern and south-central parts of the study area and by outcrops of Littlefield Rhyolite along the central and eastern portions. Miocene basalt, tuff, and rhyolite underlie Pliocene basalt and Quaternary fanglomerate, landslide deposits, and alluvium. Faulting is quite extensive in the study area and diatomite beds are common along the east boundary of the Gold Creek area. Opal, chalcedony, and crystalline quartz were fairly common in the stream gravels and were seen as thin veins in basalt in the northern portion of the Gold Creek WSA. An active hot spring depositing silica and carbonate sinter is located at the base of a hillside south of Highway 20 about two thirds of a mile (1.1 km) west of the mouth of Gold Creek. To the south of the spring lies a vertical, hydrothermally brecciated and recemented quartz vein. This northwest-trending vein is 2 ft (0.6 m) to 3 ft (0.9 m) in thickness.

METHODS OF STUDY

Sample Media

Analyses of the stream-sediment samples represent the chemistry of the rock material eroded from the drainage basin upstream from each sample site. Such information is useful in identifying those basins which contain concentrations of elements that may be related to mineral deposits. Heavy-mineral-concentrate samples provide information about the chemistry of certain minerals in rock material eroded from the drainage basin upstream from each sample site. The selective concentration of minerals, many of which may be ore related, permits determination of some elements that are not easily detected in stream-sediment samples.

Analyses of unaltered or unmineralized rock samples provide background geochemical data for individual rock units. On the other hand, analyses of altered or mineralized rocks, where present, may provide useful geochemical information about the major- and trace-element assemblages associated with a mineralizing system.

Sample Collection

Stream-sediment samples were collected at 42 sites and heavy-mineral-concentrate samples at 37 sites (plate 1). Rock samples were collected at 37 sites. Sampling density was about one sample site per 1 mi² (2.6 km²) for the stream sediments and heavy-mineral concentrates. The area of the drainage basins sampled ranged from .25 mi² (0.65 km²) to 5 mi² (13 km²).

Stream-sediment samples

The stream-sediment samples consisted of active alluvium collected primarily from first-order (unbranched) and second-order (below the junction of two first-order) streams as shown on USGS topographic map (plate 1). Some samples were composited from several localities within an area that may extend as much as 20 ft (6 m) from the site plotted on the map.

Heavy-mineral-concentrate samples

Heavy-mineral-concentrate samples were collected from the same active alluvium as the stream-sediment samples. Each bulk sample was screened with a 2.0-mm (10-mesh) screen to remove the coarse material. The less than 2.0-mm fraction was panned until most of the quartz, feldspar, organic material, and clay-sized material were removed.

Rock samples

Rock samples were collected from outcrops, streambeds, or float in the vicinity of the plotted site location. Descriptions of rock samples are in table 6.

Sample Preparation

The stream-sediment samples were air dried, then sieved using 80-mesh (0.17-mm) stainless-steel sieves. The portion of the sediment passing through the sieve was saved for analysis.

Samples panned in the laboratory were air dried and sieved to minus-35 mesh; bromoform (specific gravity 2.85) was used to remove the remaining quartz and feldspar. The resultant heavy-mineral sample was separated into three fractions using a large electromagnet by placing the sample in contact with the face of the magnet (in this case a modified Frantz Isodynamic Separator). The most magnetic fraction (removed at a setting of 0.25 ampere), primarily magnetite, was not analyzed. The second fraction (removed at a setting of 1.75 ampere), largely ferromagnesian silicates and iron oxides, was saved for archival storage. The third fraction (the nonmagnetic material which may include the nonmagnetic ore minerals, zircon, sphene, etc) was split using a Jones splitter. One split was hand ground for spectrographic analysis; the other split was saved for mineralogical analysis. (These magnetic separates are the same separates that would be produced by using a Frantz Isodynamic Separator set at a slope of 15° and a tilt of 10° with a current of 0.32 ampere to remove the magnetite and ilmenite, and a current of 0.6 ampere to split the remainder of the sample into paramagnetic and nonmagnetic fractions.)

Rock samples were crushed and then pulverized to minus 0.15 mm with ceramic plates.

Sample Analysis

Spectrographic method

The stream-sediment, heavy-mineral-concentrate, and rock samples were analyzed for 35 elements using semiquantitative, direct-current arc emission spectrographic methods. In addition, heavy-mineral-concentrate samples were also scanned for platinum (Pt) and palladium (Pd). The analyses were performed using a modification of the methods of Grimes and Marranzino (1968), and of Myers and others (1961). Spectrographic results were obtained by visual comparison of spectra derived from the sample against spectra obtained from standards made from pure oxides and carbonates. Standard concentrations are geometrically spaced over any given order of magnitude of concentration as follows: 100, 50, 20, 10, and so forth. Samples whose concentrations are estimated to fall between those values are assigned values of 70, 30, 15, and so forth. The precision of the analytical method is approximately plus or minus one reporting interval at the 83 percent confidence level and plus or minus two reporting intervals at the 96 percent confidence level (Motooka and Grimes, 1976). Values determined for the major elements, iron, magnesium, calcium, titanium, sodium, and phosphorus are given in weight percent; all others are given in parts per million (micrograms/gram). Analytical data for samples from the Gold Creek and Sperry Creek WSA's are listed in tables 3, 4, and 5 for stream-sediment, heavy-mineral-concentrate, and rock samples, respectively.

Chemical methods

Samples from these wilderness study areas were also analyzed by other methods. Stream sediments were analyzed for uranium (U) using fluorometry. Rock, and stream-sediments were analyzed for gold (Au) using flameless atomic absorption; for mercury (Hg) using atomic absorption and for silver (Ag), arsenic (As), gold (Au), Bismuth (Bi), Cadmium (Cd), Copper (Cu), molybdenum (Mo), lead (Pb), antimony (Sb), and zinc (Zn), using inductively coupled

plasma-atomic emission spectroscopy. Selected rock samples were analyzed for gold (Au) using atomic absorption. For a more detailed summary of these chemical methods see table 2.

Analytical results for stream-sediment, heavy-mineral concentrate, and rock samples are listed in table 3, 4, and 5 respectively.

ROCK ANALYSIS STORAGE SYSTEM

Upon completion of all analytical work, the analytical results were entered into a computer-based file called Rock Analysis Storage System (RASS). This data base contains both descriptive geological information and analytical data. Any or all of this information may be retrieved and converted to a binary form (STATPAC) for computerized statistical analysis or publication (VanTrump and Miesch, 1977).

DESCRIPTION OF DATA TABLES

Tables 3-5 list the results of analyses for the samples of stream sediment, heavy-mineral concentrate, and rock, respectively. For the three tables, the data are arranged so that column 1 contains the USGS-assigned sample numbers. These numbers correspond to the numbers shown on the site location map (plate 1). Columns in which the element headings show the letter "s" beside the element symbol are emission spectrographic analyses; "aa" indicates atomic absorption analyses; "icp" indicates inductively coupled plasma-atomic emission spectroscopy; "faa" indicates flameless atomic absorption analysis; and "f" indicates fluorometric analyses. A letter "N" in the tables indicates that a given element was looked for but not detected at the lower limit of determination shown for that element in tables 1 and 2. For emission spectrographic analyses, a "less than" symbol (<) entered in the tables in front of the lower limit of determination indicates that an element was observed but was below the lowest reporting value. For AA and ICP analyses, a "less than" symbol (<) entered in the tables in front of the lower limit of determination indicates that an element was below the lowest reporting value. If an element was observed but was above the highest reporting value, a "greater than" symbol (>) was entered in the tables in front of the upper limit of determination. If an element was not looked for in a sample, two dashes (--) are entered in tables 3-5 in place of an analytical value. Because of the formatting used in the computer program that produced table 5, some of the elements listed (Fe, Mg, Ca, Ti, Ag, Na, and Be) carry one or more nonsignificant digits to the right of the significant digits. The analysts did not determine these elements to the accuracy suggested by the extra zeros.

ACKNOWLEDGMENTS

Several of our colleagues also participated in sample collection, preparation, analysis, and data retrieval: collection, Jim Evans; preparation, Craig Motooka and Wilfrid Sadler; analyses, John Bullock; data retrieval, Shirley Ford and Mary Lou Tompkins.

Table 6. Description of rock samples

GS001A	Silicified rock
GS001B	Silicified rock, chalcedony, opal
GS003	Silicified rock, chalcedony, opal
GS004A	Basalt (outcrop)
GS004B	Basalt (outcrop)
GS005	Basalt (outcrop)
GS006	Calcite (veins)
GS009	Iron stained tuff (composite)
GS010	Opal in vesicular tuff
GS013	Yellow coating on andesite
GS014A	Hot spring black mud
GS014B	Quartz vein (float from site GS017)
GS014E	Siliceous sinter
GS014D	Orange scum on surface of hot spring
GS015A	Quartz vein (float probably from vein at site GS017)
GS015B	Calcite veins in basalt
GS015E	Basalt (outcrop)
GS016	Quartz vein cobbles (probably source = vein at site GS017)
GS017A	Basalt in contact with quartz vein
GS017B	Quartz vein (3 ft thick brecciated and recemented)
GS018A	Basalt (outcrop)
GS018B	Jasper (vein float material common on hillside to east)
GS019	Basalt (outcrop sample) along highway east of site GS019)
GS020	Aphanitic volcanic rock
GS022	Opal in andesite breccia
GS023A	Diatomaceous earth (cobbles)
GS023B	Opal and jasper
GS025	Basalt (outcrop)
GS026	Opal in rhyolite breccia
GS027	Diatomaceous earth (outcrop)
GS030A	Basalt and andesite (composite)
GS030B	Tuff (composite)
GS032	Basalt (outcrop)
GS033	Basalt (outcrop)
GS035	Basalt (outcrop)
GS038	Basalt (outcrop)
GS042	Opal in andesite(?)
G-1C	Brecciated quartz vein
G-2	Brown and red welded tuff
G-7B	Rhyolite containing yellow and red oxide and brown, yellow and green opal veins
G-10	Silicified rhyolite
G-11	Silicified rhyolite
G-12	Silicified rhyolite (yellow)
G-13	Purple and gray chalcedony vein
G-15	White quartz containing oxidized basalt fragments
G-20	Red welded tuff
G-21	Siliceous sinter

G-22	Green and brown chalcedony
G-23	Brecciated rhyolite cemented by chalcedony and opal
G-24	Green chalcedonic replacement of rhyolite, cut by black jasper
G-25	Green chalcedony
G-26A	White quartz
G-26C	Black and brown oxide
G-27	Red and yellow welded tuff
G-28	Brown and yellow iron oxide
G-29	Yellow-brown jasper
G-32B	Lithophysal welded tuff
G-33	Yellow-brown jasper
G-34	Brecciated rhyolite cemented by quartz and cut by black and brown oxide veins
G-35	Silicified and quartz veined rhyolite
G-36	Brecciated rhyolite with yellow siliceous cement
G-37	Brown jasper
G-39	Dark gray siliceous sinter containing brown iron oxide
G-40	Brecciated and oxidized rhyolite
G-41	Yellow chalcedony
G-42	Brecciated rhyolite cemented with friable yellow and brown material
G-44	Palagonite breccia
G-46	Friable yellow cement in basalt breccia
G-49	Yellow-brown jasper
